1. Introduction

The buried pipes are frequently analyzed by using numerical methods [1-3]. In numerical model of a buried pipe the plane strain condition is used.

Analytical method for the determination of stress state in a pipe subjected to internal pressure at plane strain condition and elasto plastic loading for incompressible material (Poisson’s ratio \(\nu = 0.5\)) is presented in work [4]. In this case tensile curve of material in elasto plastic loaded zone is approximated by linear function. Radial and circumference stresses in work [4] are determined by the dependencies [1]:

\[
\sigma_{r,p} = \frac{E}{\sqrt{3}} \left( 1 - \frac{E}{E_p} \right) \left( 2 \ln \frac{r}{r_p} + \frac{1}{2} \right) + \frac{E}{E_p} \frac{r_p^2}{r_s^2} \frac{E_s}{E} \frac{r_s^2}{r^2} \tag{1}
\]

where \(E\) is modulus of elasticity; \(r_p\) is maximum pipe radius of elasto plastically deformed zone; \(r_s\) is external radius of the pipe; \(E_s\) is modulus of elasticity; \(E_p\) is hardening modulus of the material in elasto plastic zone.

The stress strain state components calculated analytically when \(\nu = 0.5\) [4] and determined by FEA (finite element analysis) when \(\nu = 0.3\) are shown in Fig. 1. In this case stress strain components mostly differ at external surface of the pipe: \(\sigma_r - 2\%\), \(\sigma_\theta - 1.5\%\), \(\sigma_z - 70\%\), \(\sigma_r - 1.5\%\), \(\varepsilon_r - 85\%\), \(\varepsilon_\theta - 15\%\) and \(\varepsilon_z - 3\%\). Therefore, the method presented in work [4] is inapplicable for the investigation of radial stiffness of a pipe under elasto plastic loading.

The analytical method for stress strain state determination in homogeneous pipe subjected to elasto plastic loading at plane strain condition with taking into account compressibility of the material (\(\nu \leq 0.5\)) is presented in this paper.

2. Determination of stress strain state components in homogeneous pipe at elasto plastic loading

The solution is made by using the relative parameters: \(\rho = r/r_{in}\), \(s = \delta r_{in}\), \(\rho_u = 1\), \(\rho_s = r_{ex}/r_{in} = 1 + s\), \(\xi = x/\delta\) (0 \(\leq \xi \leq 1\), \(\rho = (r_0 + x)/r_{in} = 1 + \xi s\) (Fig. 2).

The load is determined by using relative coordinate \(e_{pl}\) which denotes the maximum value of elasto plastically deformed zone.

Stress intensity at plane strain condition

\[
\sigma_i = \sqrt{\sigma_r^2 + \sigma_\theta^2 + \sigma_z^2 - \sigma_r \sigma_\theta - \sigma_r \sigma_z - \sigma_\theta \sigma_z} \quad \tag{3}
\]

By estimating that \(\sigma_i = \nu (\sigma_r + \sigma_\theta)\)

\[
\sigma_i = \sqrt{(\sigma_\theta - \sigma_r)^2 - \nu (1 - \nu)(\sigma_\theta + \sigma_r)^2 + \sigma_r \sigma_\theta} \quad \tag{4}
\]

Fig. 1 Distribution of stress (a) and strain (b) components in the thickness of pipe wall \(\delta\) when \(E_l/E = 0.2\) and \(r_p = (r_{in} + r_{ex})/2\): (-----) obtained analytically when \(\nu = 0.5\); (-----) determined by FEA when \(\nu = 0.3\) and \(\nu' < 0.5\) (\(\nu'\) is effective Poisson’s ratio)

Fig. 2 Scheme of homogeneous pipe subjected to internal pressure at plane strain condition

\(\rho_{in}\) lower index \(p\) denotes values at elasto plastic loaded zone
\(\rho_{ex}\) lower index \(e\) denotes values at elastic loaded zone

1 lower index \(p\) denotes values at elasto plastic loaded zone
lower index \(e\) denotes values at elastic loaded zone
Strain intensity at plane strain condition

\[ e_i = \frac{1}{1 + v} \sqrt{e_r^2 + e_\theta^2 - e_r e_\theta} \]  \hspace{1cm} (5)

In elasto plastically loaded zone in Eqs. (4) and (5) instead of \( v \) must be used effective Poisson’s ratio

\[ v' = 0.5 - (0.5 - v) \frac{E'}{E} \]  \hspace{1cm} (6)

where \( E' = \sigma_{pl}/e_{pl} \) is secant modulus of material tensile curve.

In elastic loaded zone radial and circumference stresses may be determined by Lame’s equations \([5] \) \(^2\)

\[
\begin{align*}
\sigma_r &= \frac{p}{2(2 + s)} \left[ 1 + \frac{s}{1 + \xi s} \right] \left[ 1 + \frac{1 + s}{1 + \xi s} \right]^{(1 + 2v)^2} \\
\sigma_\theta &= \frac{p}{2(2 + s)} \left[ 1 + \frac{s}{1 + \xi s} \right]^{(1 + 2v)^2} 
\end{align*}
\]  \hspace{1cm} (7)

where \( p_e \) is inner pressure when it is assumed that the material is deformed only elastically (Eq. 10).

By taking into account Eqs. (4) and (7) the stress intensity at elastic loading

\[ \sigma_{ie}(\xi) = \frac{p_e}{s(2 + s)} \left[ 3 \left( \frac{1 + s}{1 + \xi s} \right)^4 + (1 - 2v)^2 \right] \]  \hspace{1cm} (8)

Elasto plastic strains in the pipe appear when

\[ p > p_{e max} = \frac{\sigma_{pl} s(2 + s)}{\sqrt{3(1 + s)^4 + (1 - 2v)^2}} \]  \hspace{1cm} (9)

It is assumed that in elastically deformed zone, when \( p > p_{e max} (\xi_0 > 0) \), behavior of material is the same as in elastic loading. Therefore in elastically deformed zone for determination of stresses the fictitious inner pressure

\[ p_{ef} = \frac{\sigma_{pl} s(2 + s)}{\sqrt{3 \left( \frac{1 + s}{1 + \xi s} \right)^4 + (1 - 2v)^2}} \]  \hspace{1cm} (10)

is used, i.e. in Eqs. (7) and (8) when \( \xi \geq \xi_0 \), instead of \( p_e \) the value \( p_{ef} \) must be used.

In elasto plastically loaded zone strain intensity \( e_{ip} \) is calculated from the presumption, that the potential energy for elastic and elasto plastic loading is the same \([6] \) (Fig. 3)

\[ \frac{1}{2} e_{ip}, \sigma_{ie} = \frac{1}{2} e_i, \sigma_{pl} + \int_{\xi_0}^{\xi} \sigma_{ip} \, de_{ip} \]  \hspace{1cm} (11)

From Eq. (11) follows that when tension curve of the material in elasto plastically loaded zone is approximated by power function

\[ e_{ip}(\xi) = \sigma_{pl} \left\{ 1 + \left( \frac{m_0 + 1}{2 \sigma_{pl}} \right) \left[ \sigma_{ie}(\xi) - \sigma_{pl} \right] \right\}^{\frac{1}{m_0+1}} \]  \hspace{1cm} (12)

and when approximated linearly –

\[ e_{ip}(\xi) = \frac{\sigma_{pl}}{E} \left\{ 1 - E_i \left[ 1 - \frac{1}{E_i} \left( \frac{\sigma_{ie}(\xi)}{\sigma_{pl}} - 1 \right) \right] \right\} \]  \hspace{1cm} (13)

where \( \xi \leq \xi_0 \); in this case in expression of \( \sigma_{ie}(\xi) \), i.e. in Eq. (8) instead of \( v \) must be used \( v' \); \( m_0 \) is power index of material hardening in elastoplastic zone.

At elastoplastic loading stress intensity

\[ \sigma_{ip}(\xi) = \sigma_{pl} \left( \frac{e_{ip}(\xi)}{e_{pl}} \right)^{m_0} \]  \hspace{1cm} (14)

or

\[ \sigma_{ip}(\xi) = \sigma_{pl} + \left[ e_{ip}(\xi) - e_{pl} \right] E_i \]  \hspace{1cm} (15)

When material of the pipe is deformed elasto plastically and \( \sigma_{ie}(\xi) = \sigma_{pl} \), the inner pressure can be calculated form the assumption that mean elastic circumference stress expressed in term of \( p \) is equal to the mean circumference stress, when elastoplastic loading appears (Fig. 4), i.e.

\[ \int_0^1 \sigma_{ip}(\xi, p) \, d\xi = \int_0^\gamma p \sigma_{ip}(\xi) \, d\xi + \int_{\gamma}^1 \sigma_{ip}(\xi) \, d\xi \]  \hspace{1cm} (16)

where \( \sigma_{ip}(\xi, p) \) is circumference stress calculated form Eq. (7) by substituting \( p \) instead of \( p_e \).

---

\(^2\) upper index \( L \) denote Lame’s equation
Determination of $\int_0^z \sigma_{r,\theta}(\xi) d\xi$ is complicated. Therefore, in this work it is accepted that

$$\int_0^z \sigma_{r,\theta}(\xi) d\xi = \frac{1}{2} \frac{\xi_p}{\xi_p} \left[ \sigma_{r,\theta}(0) + \sigma_{r,\theta}^{*}(\xi_p) \right]$$

(17)

where $\sigma_{r,\theta}(0)$ is calculated by approaching method form Eq. (20), when $\sigma_{r,\theta}(0) = -p$

Then Eq. (16) can be written

$$p = \frac{s}{2} \left[ \sigma_{r,\theta}(0) + \sigma_{r,\theta}^{*}(\xi_p) \right] + \sigma_{r,\theta}^{*}(\xi_p) \frac{1 - \xi_p}{\xi_p} \frac{1 + \xi_p}{s} + \frac{p_s}{(1 + \xi_p) s}$$

(18)

The values of radial stresses $\sigma_r$ in two points of elasto plasticly loaded zone are known: $\sigma_{r,\theta}(0) = -p$ and $\sigma_{r,\theta}^{*}(\xi_p)$. In other points of elasto plasticly loaded zone stress $\sigma_r$ is calculated by assuming that it is distributed linearly

$$\sigma_{r,\theta}(\xi) = \frac{\sigma_{r,\theta}^{*}(\xi_p)}{\xi_p} \xi - \frac{\sigma_{r,\theta}^{*}(\xi_p)}{\xi_p} \xi$$

(19)

When $\sigma_{r,\theta}(\xi)$ and $\sigma_{r,\theta}^{*}(\xi)$ are known the circumference stress at elasto plasticly loaded zone can be calculated from Eq. (4)

$$\sigma_{r,\theta}(\xi) = \frac{\sigma_{r,\theta}^{*}(\xi_p)(1 + 2 C_r)}{2(1 - C_r)} + \frac{3 \sigma_{r,\theta}^{*}(\xi_p)(4 C_r - 1)}{4(1 - C_r)^2} + \frac{\sigma_{r,\theta}^{*}(\xi)}{(1 - C_r)}$$

(20)

where $C_r = v(1 - v)$.

For stress strain state determination in any point of the pipe at elasto plasticly loading, when $\xi_p$ is known, the inner pressure $p$ must be determined in this way:

- $p_s$ from Eq. (10) is calculated;
- $e_{r,\theta}(0)$, $\sigma_{r,\theta}(0)$ and $v^*$ by approaching method from Eqs. (12), (14) or (13), (15) and (6) are calculated. For the determination of $\sigma_{r,\theta}(0)$ by Eq. (8) instead of $v$ must be used $v^*$. In first approaching can be assumed $v^* = v$;
- $p$ and $\sigma_{r,\theta}(0)$ are determined by approaching method from Eqs. (18), (20) and taking into account $\sigma_{r,\theta}(0) = -p$.

In first approaching can be assumed $p = p_s(1 - 0.2 \xi_p)$.

The stress cleaning components in elasto plasticly loaded zone ($\xi \leq \xi_p$) are determined in this way:

- $e_{r,\theta}(\xi)$, $\sigma_{r,\theta}(\xi)$ and $v^*$ by approaching method from Eqs. (12), (14) or (13), (15) and (6) are determined. In expression of $\sigma_{r,\theta}(\xi)$, i.e. in Eq. (8) instead of $v$ must be used $v^*$.
- $\sigma_{r,\theta}(\xi)$, $\sigma_{r,\theta}(\xi)$ and $\sigma_{r,\theta}(\xi)$ stresses are calculated from Eqs. (19), (20) and (4).

Stresses in elasto plasticly loaded zone ($\xi \geq \xi_p$) are calculated form Eqs. (7) and (8) by using $p_s$ instead of $p_{s}$.

Strains $e_r$, $e_\theta$ are calculated by generalized Hooke’s law. In elasto plasticly loaded zone the $v^*$ and $E'$ must be used instead of $v$ and $E$.

3. Stresses and strains investigations at elasto plastic loading

Dependence of stress strain state components distribution on $\xi_p$ are shown in Fig. 5 and 6. In elasto plasticly deformed zone with increasing of $\xi$ stresses $\sigma_r$, $\sigma_\theta$, $\sigma_\xi$ increase while strains and stress intensity $\sigma_\xi$ decreases.

Comparison of stress strain components obtained analytically and determined by FEA is presented in Table. The disagreement increases with increasing elasto plasticly deformed zone. When elasto plasticly deformed zone increases up to 2/3 of wall thickness the disagreement for stresses is up to 4.5% and for strains – 5.5%. When elasto plasticly deformed zone does not exceed mean radius of the pipe wall ($\xi_p \leq 0.5$) disagreement for the stresses is up to 3.0% and for strains – 1.5%.

When the pipe is loaded elasto plasticly a negligible increase of inner pressure caused extensive increase of elasto plasticly deformed zone (see Fig. 6). For example, for the pipe with $s = 0.4$, in order to reach plastic zone from $\xi_p = 0.5$ to $\xi_p = 1.0$ the inner pressure must increase only 1.106 times and for the pipe with $s = 0.2 – 1.054$ times. Analogous results were obtained in work [7]. When elasto plasticly deformed zone reaches the external surface of the pipe wall the stability of the structure may be loosened. Therefore, in design of pipelines it is recommended that under instantaneous overloading the elasto plasticly deformed zone should not exceed the mean radius of the pipe wall.

Fig. 5 Dependences of strains distribution on $\xi_p$ in the thickness of pipe wall determined analytically (——) and by FEA (-----) when $s = 0.4$, $v = 0.3$ and $m_0 = 0.15$: a – radial strain $e_r$; b – circumference strain $e_\theta$; c – strain intensity $e_\xi$.

Fig. 6 Dependences of stresses distribution on ξ in the thickness of pipe wall determined analytically (——) and by FEA (---) when s = 0.4, v = 0.3 and m₀ = 0.15: a – radial stress σᵣ; b – circumference stress σ₀; c – axial stress σᵢ; d – stress intensity σᵣ.

Table
Dependence of stress strain state components distribution on Poison’s ratio $\nu$ is shown in Figs. 7 and 8. With increasing $\nu$ the axial stress $\sigma_z$ and radial strain $e_r$ increases, circumference stress $\sigma_\theta$ increases negligibly, circumference strain $e_\theta$ at inner radius of the pipe negligibly increases and at external radius decreases. Radial stress $\sigma_r$, intensities $\sigma_i$ and $e_i$ practically does not depend on $\nu$. In this case disagreement between stress state components values obtained by the method presented in this paper and determined by FEA does not exceed 3.0% and strains 2.0%.

Under elasto plastic loading and cyclic characteristics of the material are related [6, 8]. Therefore, the dependencies presented in this work enable to increase accuracy of the buried pipelines durability determination.

4. Conclusions

Dependencies for stresses and strains determination in homogeneous pipe subjected to internal pressure at elasto plastic loading, plane strain condition and taking into account compressibility of the pipe material are presented in this paper. By FEA it is proved that accuracy of these dependencies is quite acceptable.

In design of pipelines it is recommended that under instantaneous overloading the elasto plastically deformed zone does not exceed the mean radius of pipe wall ($\xi_p \leq 0.5$).

With increasing Poison’s ratio $\nu$ the axial stress $\sigma_z$ and radial strain $e_r$ increases, circumference stress $\sigma_\theta$ increases negligibly, circumference strain $e_\theta$ at inner radius
of pipe negligibly increases and at external radius – decreases. Radial stress $\sigma_r$, stress intensity $\sigma_i$ and strain intensity $e_i$ practically does not depend on $v$ (for example, when $v$ changes by 40%, the $\sigma_r$ changes only by 1.4%, $\sigma_i$ – 1.1% and $e_i$ – 1.3%).

DETERMINATION OF STRESS STRAIN STATE IN PIPE SUBJECTED TO INTERNAL PRESSURE AT PLANE STRAIN CONDITION UNDER ELASTO PLASTIC LOADING

S u m m a r y

The stress strain state of homogeneous pipe subjected to internal pressure at elasto plastic loading and plane strain condition is analyzed. The plane strain condition appears in buried pipelines. By using FEA it is proved that the accuracy of presented methodic for determination of stresses and strains is quite acceptable. Dependences of stress strain state components distribution on value of inner pressure and Poisson’s ratio are also presented.
